## On Robin's criterion for the Riemann Hypothesis

**Frank Vega** 

the date of receipt and acceptance should be inserted later

Abstract Robin's criterion states that the Riemann hypothesis is true if and only if the inequality  $\sigma(n) < e^{\gamma} \times n \times \log \log n$  holds for all natural numbers n > 5040, where  $\sigma(n)$  is the sum-of-divisors function of n and  $\gamma \approx 0.57721$  is the Euler-Mascheroni constant. In 2022, Vega stated that the possible existence of the smallest counterexample n > 5040 of the Robin inequality implies that  $q_m > e^{31.018189471}$  and  $(\log n)^{\beta} < 1000$ ample n > 5040 of the Köbin inequality implies that  $q_m > 0$   $1.03352795481 \times \log(N_m)$ , where  $N_m = \prod_{i=1}^m q_i$  is the primorial number of order m,  $q_m$  is the largest prime divisor of n and  $\beta = \prod_{i=1}^m \frac{q_i^{a_i+1}}{q_i^{a_i+1}-1}$  when n must be an Hardy-

Ramanujan integer of the form  $\prod_{i=1}^{m} q_i^{a_i}$ . Based on that result, we obtain a contradiction just assuming the existence of such possible smallest counterexample n > 5040for the Robin inequality. By contraposition, we show that the Riemann hypothesis should be true.

### **1** Introduction

In mathematics, the Riemann hypothesis is a conjecture that the Riemann zeta function has its zeros only at the negative even integers and complex numbers with real part  $\frac{1}{2}$ . As usual  $\sigma(n)$  is the sum-of-divisors function of *n*:

 $\sum_{d|n} d$ 

F. Vega

CopSonic, 1471 Route de Saint-Nauphary 82000 Montauban, France ORCiD: 0000-0001-8210-4126 E-mail: vega.frank@gmail.com

where  $d \mid n$  means the integer d divides n and  $d \nmid n$  means the integer d does not divide n. Define f(n) to be  $\frac{\sigma(n)}{n}$ . Say Robins(n) holds provided

$$f(n) < e^{\gamma} \times \log \log n.$$

The constant  $\gamma \approx 0.57721$  is the Euler-Mascheroni constant and log is the natural logarithm. The importance of this property is:

**Theorem 1.1** Robins(*n*) holds for all natural numbers n > 5040 if and only if the Riemann hypothesis is true [3].

It is known that Robins(n) holds for many classes of numbers *n*. We recall that an integer *n* is said to be square free if for every prime divisor *q* of *n* we have  $q^2 \nmid n$ .

**Theorem 1.2** Robins(*n*) holds for all natural numbers n > 5040 that are square free [1].

Let  $q_1 = 2, q_2 = 3, ..., q_m$  denote the first *m* consecutive primes, then an integer of the form  $\prod_{i=1}^m q_i^{a_i}$  with  $a_1 \ge a_2 \ge \cdots \ge a_m \ge 0$  is called an Hardy-Ramanujan integer [1]. Now, we are able to use this recently result:

**Theorem 1.3** The possible existence of the smallest counterexample n > 5040 of the Robin inequality implies that  $q_m > e^{31.018189471}$  and  $(\log n)^{\beta} < 1.03352795481 \times \log(N_m)$ , where  $N_m = \prod_{i=1}^m q_i$  is the primorial number of order m,  $q_m$  is the largest prime divisor of n and  $\beta = \prod_{i=1}^m \frac{q_i^{a_i+1}}{q_i^{a_i+1}-1}$  when n must be an Hardy-Ramanujan integer of the form  $\prod_{i=1}^m q_i^{a_i}$  [4].

Putting all together yields a proof for the Riemann hypothesis using the Theorem 1.3 as the principal argument.

### 2 A Central Lemma

These are known results:

**Lemma 2.1** *For every* x > -1 *[2]:* 

$$x \ge \log(1+x) \ge \frac{x}{x+1}.$$

**Lemma 2.2** For every real number x [2]:

$$e^x \ge 1+x$$

The following is a key Lemma.

**Lemma 2.3** If the natural number n > 5040 is an Hardy-Ramanujan integer of the form  $\prod_{i=1}^{m} q_i^{a_i}$ , then  $\beta \ge 1 + \sum_{i=1}^{m} \frac{1}{q_i^{a_i+1}}$  where  $\beta = \prod_{i=1}^{m} \frac{q_i^{a_i+1}}{q_i^{a_i+1}-1}$ .

*Proof* If we apply the logarithm to the value of

$$\prod_{i=1}^{m} \frac{q_i^{a_i+1}}{q_i^{a_i+1} - 1}$$

then we obtain that

$$\sum_{i=1}^{m} \log(\frac{q_i^{a_i+1}}{q_i^{a_i+1}-1})$$

For some  $1 \le j \le m$ , we know that

$$\frac{q_j^{a_j+1}}{q_j^{a_j+1}-1} = 1 + \frac{1}{q_j^{a_j+1}-1}.$$

We use the Lemma 2.1 to show that

$$\begin{split} \log(1+\frac{1}{q_{j}^{a_{j}+1}-1}) &\geq \frac{\frac{1}{q_{j}^{a_{j}+1}-1}}{\frac{1}{q_{j}^{a_{j}+1}-1}+1} \\ &= \frac{1}{(q_{j}^{a_{j}+1}-1) \times (\frac{1}{q_{j}^{a_{j}+1}-1}+1)} \\ &= \frac{1}{1+(q_{j}^{a_{j}+1}-1)} \\ &= \frac{1}{q_{j}^{a_{j}+1}}. \end{split}$$

So,

$$\sum_{i=1}^{m} \log(\frac{q_i^{a_i+1}}{q_i^{a_i+1}-1}) \ge \sum_{i=1}^{m} \frac{1}{q_i^{a_i+1}}$$

and thus,

$$\prod_{i=1}^{m} \frac{q_i^{a_i+1}}{q_i^{a_i+1}-1} \ge e^{\sum_{i=1}^{m} \frac{1}{q_i^{a_i+1}}}$$

Using the Lemma 2.2, we have that

$$e^{\sum_{i=1}^{m}rac{1}{q_{i}^{a_{i}+1}}} \ge 1 + \sum_{i=1}^{m}rac{1}{q_{i}^{a_{i}+1}}$$

and therefore,

$$eta \geq 1+\sum_{i=1}^m rac{1}{q_i^{a_i+1}}.$$

## 3 Main Insight

This is the main insight.

**Lemma 3.1** Suppose that n > 5040 is an Hardy-Ramanujan integer of the form  $\prod_{i=1}^{m} q_i^{a_i}$  and  $q_m > e^{31.018189471}$ . Then  $(\log n)^{\sum_{i=1}^{m} \frac{1}{q_i^{a_i+1}}} \ge 1.03352795481$ .

Proof If we apply the logarithm to the both sides of the inequality, then

$$\left(\sum_{i=1}^m \frac{1}{q_i^{a_i+1}}\right) \times \log\log n \ge \log(1.03352795481).$$

Let's multiply the both sides of the inequality by  $e^{\gamma}$ ,

$$\left(\sum_{i=1}^{m} \frac{1}{q_i^{a_i+1}}\right) \times e^{\gamma} \times \log \log n \ge e^{\gamma} \times \log(1.03352795481).$$

From the Theorem 1.2, we know that

$$e^{\gamma} \times \log \log n \ge e^{\gamma} \times \log \log N_m$$
  
 $> f(N_m)$   
 $= \prod_{i=1}^m (1 + \frac{1}{q_i})$ 

since n > 5040 is an Hardy-Ramanujan integer,  $N_m = \prod_{i=1}^m q_i$  is the primorial number of order *m* and thus,  $n \ge N_m$  and  $N_m$  is square free. Hence, we would have that

$$\left(\sum_{i=1}^{m} \frac{1}{q_i^{a_i+1}}\right) \times \prod_{i=1}^{m} (1+\frac{1}{q_i}) \ge e^{\gamma} \times \log(1.03352795481).$$

If we apply the logarithm to the both sides again, then

$$\log\left(\sum_{i=1}^{m} \frac{1}{q_i^{a_i+1}}\right) + \sum_{i=1}^{m} \log(1+\frac{1}{q_i}) \ge \log(e^{\gamma} \times \log(1.03352795481)).$$

We use the Lemma 2.1 to show that

$$-1 + \sum_{i=1}^{m} \frac{1}{q_i^{a_i+1}} \ge \log\left(1 + (-1 + \sum_{i=1}^{m} \frac{1}{q_i^{a_i+1}})\right) = \log\left(\sum_{i=1}^{m} \frac{1}{q_i^{a_i+1}}\right)$$

since

$$-1 + \sum_{i=1}^{m} \frac{1}{q_i^{a_i+1}} > -1.$$

For some  $1 \le j \le m$ , we know that

$$\log(1 + \frac{1}{q_j}) \ge \frac{\frac{1}{q_j}}{\frac{1}{q_j} + 1}$$
$$= \frac{1}{q_j \times (\frac{1}{q_j} + 1)}$$
$$= \frac{1}{1 + q_j}$$

according to the Lemma 2.1. However, we note that

$$-1 + \sum_{i=1}^{m} \frac{1}{q_i^{a_i+1}} + \sum_{i=1}^{m} \frac{1}{1+q_i} \gg 0$$

when  $q_m > e^{31.018189471}$ , where the symbol  $\gg$  means "much greater than". In addition, we have that

$$0 > \log(e^{\gamma} \times \log(1.03352795481))$$

and finally, the proof is complete.

#### 4 Main Theorem

We conclude with the following statement:

Theorem 4.1 The Riemann hypothesis is true.

*Proof* Suppose that n > 5040 is the possible smallest number such that Robins(n) does not hold. By the Theorem 1.3, we know that  $q_m > e^{31.018189471}$  and  $(\log n)^{\beta} < 1.03352795481 \times \log(N_m)$ , where  $N_m = \prod_{i=1}^m q_i$  is the primorial number of order m,  $q_m$  is the largest prime divisor of n and  $\beta = \prod_{i=1}^m \frac{q_i^{a_i+1}}{q_i^{a_i+1}-1}$  when n must be an Hardy-Ramanujan integer of the form  $\prod_{i=1}^m q_i^{a_i}$ . From the Lemma 2.3, we know that

$$(\log n)^{eta} \geq (\log n)^{\left(1+\sum_{i=1}^{m} rac{1}{q_i^{a_i+1}}
ight)}$$

and therefore, we would have that

$$(\log n)^{\left(1+\sum_{i=1}^{m} \frac{1}{q_{i}^{a_{i}+1}}\right)} < 1.03352795481 \times \log(N_{m})$$

when n > 5040 is the possible smallest number such that Robins(n) does not hold. Thus, we would obtain that

$$(\log n)^{\sum_{i=1}^{m} \frac{1}{q_i^{a_i+1}}} < 1.03352795481$$

since *n* must be an Hardy-Ramanujan integer and so,  $\log n \ge \log N_m$ . However, we know the previous inequality cannot be satisfied because of the Lemma 3.1. By contraposition, we show that the Riemann hypothesis is true, since we obtain a contradiction just assuming the possible smallest counterexample for the Robin inequality greater than 5040. Certainly, this is a direct consequence of the Theorem 1.1.
