Abstract

Logic Programs with Ordered Disjunction (LPOD) is an extension of standard answer set programs to handle preference using the construct of ordered disjunction, and CR-Prolog₂ is an extension of standard answer set programs with consistency restoring rules and LPOD-like ordered disjunction. We present reductions of each of these languages into the standard ASP language, which gives us an alternative way to understand the extensions in terms of the standard ASP language.

1 Introduction

In answer set programming, each answer set encodes a solution to the problem that is being modeled. There is often a need to express that one solution is preferable to another, so several extensions of answer set programs were made to express a qualitative preference over answer sets. In Logic Programs with Ordered Disjunction (LPOD) (Brewka 2002), this is done by introducing the construct of ordered disjunction in the head of a rule: \( A \times B \leftarrow \text{Body} \) intuitively means, when \( \text{Body} \) is true, if possible then \( A \), but if \( A \) is not possible, then at least \( B \). Proposition 2 from (Brewka 2002) states that there is no reduction of LPOD to disjunctive logic programs (Gelfond and Lifschitz 1991) based on the fact that the answer sets of disjunctive logic programs are subset-minimal whereas LPOD answer sets are not necessarily so. However, this justification is limited to translations that preserve the underlying signature, and it remained an open question if it is possible to turn LPOD into the language of standard ASP such as ASP-Core 2 (Calimeri et al. 2012) by using auxiliary atoms. In this paper, we provide a positive answer to this question.

We present a reduction of LPOD to standard answer set programs by compiling away ordered disjunctions. The translation gives us an alternative way to understand the semantics of LPOD in terms of the standard ASP language, and more generally, a method to express preference relations among answer sets. Instead of iterating the generator and the tester programs as in (Brewka et al. 2002), our reduction is one-pass: the preferred answer sets can be computed by calling an answer set solver one time.

It turns out that the translation idea is not restricted to LPOD but also applies to CR-Prolog₂ (Balduccini and Mellarkod 2004), which not only has a construct similar to ordered disjunction in LPOD but also inherits the construct of consistency-restoring rules—rules that can be added to make inconsistent programs to be consistent—from CR-Prolog (Balduccini and Gelfond 2003). With some modifications to the LPOD translation, we show that CR-Prolog₂ programs can also
be turned into standard answer set programs by compiling away both ordered disjunctions and consistency-restoring rules.

The paper is organized as follows. Section 2 reviews LPOD and presents a translation that turns LPOD into standard answer set programs. Section 3 reviews CR-Prolog and presents a translation that turns CR-Prolog into standard answer set programs. The complete proofs are in the supplementary material at the TPLP archives (Lee and Yang 2018).

2 LPOD to ASP with Weak Constraints

2.1 Review: LPOD

We review the definition of LPOD by Brewka (2002). As in that paper, for simplicity, we assume the underlying signature is propositional.

Syntax: A (propositional) LPOD $\Pi$ is $\Pi_{reg} \cup \Pi_{od}$, where its regular part $\Pi_{reg}$ consists of usual ASP rules $\text{Head} \leftarrow \text{Body}$, and its ordered disjunction part $\Pi_{od}$ consists of LPOD rules of the form

$$C^1 \times \cdots \times C^n \leftarrow \text{Body}$$

in which $C^i$ are atoms, $n$ is at least 2, and $\text{Body}$ is a conjunction of atoms possibly preceded by $\text{not}$. Rule (1) intuitively says “when $\text{Body}$ is true, if possible then $C^1$; if $C^1$ is not possible then $C^2$; . . . ; if all of $C^1, \ldots, C^{n-1}$ are not possible then $C^n$.”

Semantics: For an LPOD rule (1), its $i$-th option $(i = 1, \ldots, n)$ is defined as

$$C^i \leftarrow \text{Body}, \text{not } C^1, \ldots, \text{not } C^{i-1}.$$ 

A split program of an LPOD $\Pi$ is obtained from $\Pi$ by replacing each rule in $\Pi_{od}$ by one of its options. A set $S$ of atoms is a candidate answer set of $\Pi$ if it is an answer set of a split program of $\Pi$.

Example 1
(From (Brewka 2002)) The following LPOD $\Pi_1$,

$$a \times b \leftarrow \text{not } c$$
$$b \times c \leftarrow \text{not } d,$$

has four split programs:

$$a \leftarrow \text{not } c$$
$$b \leftarrow \text{not } d$$
$$b \leftarrow \text{not } c, \text{not } a$$
$$b \leftarrow \text{not } d$$

$$a \leftarrow \text{not } c$$
$$c \leftarrow \text{not } d, \text{not } b$$
$$b \leftarrow \text{not } c, \text{not } a$$
$$c \leftarrow \text{not } d, \text{not } b.$$

Each of them has the following answer sets respectively, which are the candidate answer sets of $\Pi_1$.

$$\{a, b\}$$
$$\{c\}$$
$$\{b\}, \{c\}.$$

1 In (Brewka 2002), a usual ASP rule is viewed as a special case of a rule with ordered disjunction when $n = 1$ but in this paper, we distinguish them. This simplifies the presentation of the translation and also allows us to consider LPOD that are more general than the original definition by allowing modern ASP constructs such as aggregates.
A candidate answer set \( S \) of \( \Pi \) is said to satisfy rule \( (1) \)

- to degree 1 if \( S \) does not satisfy \( Body \), and
- to degree \( j \) \((1 \leq j \leq n)\) if \( S \) satisfies \( Body \) and \( j = \min\{k \mid C^k \in S\} \).

When \( \Pi_{od} \) contains \( m \) LPOD rules, the satisfaction degree list of a candidate answer set \( S \) of \( \Pi \) is \((d_1, \ldots, d_m)\) where \( d_i \) is the degree to which \( S \) satisfies rule \( i \) in \( \Pi_{od} \). For a candidate answer set \( S \), let \( S'(\Pi) \) denote the set of rules in \( \Pi_{od} \) satisfied by \( S \) to degree \( i \). For candidate answer sets \( S_1 \) and \( S_2 \) of \( \Pi \), Brewka (2005) introduces the following four preference criteria.

1. **Cardinality-Preferred**: \( S_1 \) is cardinality-preferred to \( S_2 \) \((S_1 >_c S_2)\) if there is a positive integer \( i \) such that \(|S'_i(\Pi)| > |S'_j(\Pi)|\), and \(|S'_i(\Pi)| = |S'_j(\Pi)|\) for all \( j < i \).

2. **Inclusion-Preferred**: \( S_1 \) is inclusion-preferred to \( S_2 \) \((S_1 >^i S_2)\) if there is a positive integer \( i \) such that \( S'_i(\Pi) \subset S'_j(\Pi) \), and \( S'_i(\Pi) = S'_j(\Pi) \) for all \( j < i \).

3. **Pareto-Preferred**: \( S_1 \) is Pareto-preferred to \( S_2 \) \((S_1 >^p S_2)\) if there is a rule that is satisfied to a lower degree in \( S_1 \) than in \( S_2 \), and there is no rule that is satisfied to a lower degree in \( S_2 \) than in \( S_1 \).

4. **Penalty-Sum-Preferred**: \( S_1 \) is penalty-sum-preferred to \( S_2 \) \((S_1 >^{ps} S_2)\) if the sum of the satisfaction degrees of all rules is smaller in \( S_1 \) than in \( S_2 \).

A candidate answer set \( S \) of \( \Pi \) is a \( k \)-preferred \((k \in \{c, i, p, ps\})\) answer set if there is no candidate answer set \( S' \) of \( \Pi \) such that \( S' >^k S \).

**Example 1 (Continued)**
Recall that \( \Pi_1 \) has three candidate answer sets: \( \{a, b\} \), \( \{b\} \), and \( \{c\} \). Their satisfaction degree lists are \((1,1)\), \((2,1)\), and \((1,2)\), respectively. One can check that \( \{a, b\} \) is the only preferred answer set according to any of the four preference criteria.

**Example 2**
To illustrate the difference among the four preference criteria, consider the following LPOD \( \Pi_2 \) about picking a hotel near the Grand Canyon. \( hotel(1) \) is a 2 star hotel but is close to the Grand Canyon, \( hotel(2) \) is a 3 star hotel and the distance is medium, and \( hotel(3) \) is a 4 star hotel but is too far.

\[
\text{close} \times \text{med} \times \text{far} \times \text{tooFar} \quad \bot \leftarrow hotel(2), not \text{med} \\
\text{star4} \times \text{star3} \times \text{star2} \quad \bot \leftarrow hotel(2), not \text{star3} \\
1\{hotel(X): X = 1..3\}1 \quad \bot \leftarrow hotel(3), not \text{tooFar} \\
\bot \leftarrow hotel(1), not \text{close} \quad \bot \leftarrow hotel(3), not \text{star4} \\
\bot \leftarrow hotel(1), not \text{star2}
\]

\( \Pi_2 \) has \( 4 \times 3 \) split programs but only the following three programs are consistent (The regular part of \( \Pi_2 \) is not listed).

\[
\text{close} \leftarrow \text{med} \leftarrow not \text{close} \\
\text{star2} \leftarrow not \text{star4}, not \text{star3} \quad \text{star3} \leftarrow not \text{star4} \\
\text{tooFar} \leftarrow not \text{close}, not \text{med}, not \text{far} \quad \text{star4}
\]

The candidate answer sets of \( \Pi_2 \) and their satisfaction degree lists are

\[
S_1 = \{hotel(1), close, star2, \ldots\}, (1, 3) \quad S_2 = \{hotel(2), med, star3, \ldots\}, (2, 2) \\
S_3 = \{hotel(3), tooFar, star4, \ldots\}, (4, 1)
\]
By definition, the cardinality-preferred answer set is $S_1$, the inclusion-preferred answer sets are $S_1$ and $S_3$, the Pareto-preferred answer sets are $S_1$, $S_2$ and $S_3$, while the penalty-sum-preferred answer sets are $S_1$ and $S_2$.

2.2 An Alternative Way to Generate Candidate Answer Sets: Assumption Programs

Before we describe the translation of LPOD into standard answer set programs, we consider an alternative way to generate candidate answer sets together with their “assumption degrees,” which serves as a basis of our translation.

Let $\Pi$ be an LPOD with $m$ LPOD rules. For an LPOD rule $i \ (i \in \{1, \ldots, m\})$

$$C^i_1 \times \cdots \times C^i_{n_i} \leftarrow Body_i,$$

its $x$-th assumption ($x \in \{0, \ldots, n_i\}$), denoted by $O_i(x)$, is defined as the set of ASP rules

$$\begin{align*}
body_i & \leftarrow Body_i & (4) \\
\bot & \leftarrow x = 0, \ body_i & (5) \\
\bot & \leftarrow x > 0, \ not \ body_i & (6) \\
C^j_i & \leftarrow body_i, \ x = j & (for \ 1 \leq j \leq n_i) & (7) \\
\bot & \leftarrow body_i, \ x \neq j, \ not \ C^1_i, \ldots, \ not \ C^{j-1}_i, \ C^j_i & (for \ 1 \leq j \leq n_i) & (8)
\end{align*}$$

where $body_i$ is a new, distinct atom for each LPOD rule $i$. Rules (4)—(6) ensure that the body of (3) is false iff $x = 0$. Rule (7) represents that $C^j_i$ is true under the $x$-th assumption, and rule (8) ensures that all atoms $C^1_i, \ldots, C^{j-1}_i$ are false. The last two rules together tells us that the first atom in $C^1_i, \ldots, C^{n_i}_i$ that is true is $C^j_i$. The reason we call rules (4)—(8) the $x$-th assumption is because they encode a certain assumption imposed on rule (3) in deriving each candidate answer set: $x = 0$ assumes $Body_i$ is false, whereas $x > 0$ assumes $Body_i$ is true and the $x$-th atom in the head is to be derived.

An assumption program of an LPOD $\Pi$ is obtained from $\Pi$ by replacing each rule in $\Pi_{od}$ by one of its assumptions. If each LPOD rule $i$ is replaced by its $x_i$-th assumption, we call $(x_1, \ldots, x_m)$ the assumption degree list of the assumption program.

The following proposition asserts that the candidate answer sets can be obtained from assumption programs instead of split programs.

**Proposition 1**

For any LPOD $\Pi$ of $\sigma$ and any set $S$ of atoms of $\sigma$, $S$ is a candidate answer set of $\Pi$ iff $S \cup \{\text{body}_i \mid S$ satisfies the body of rule $i$ in $\Pi_{od}\}$ is an answer set of some assumption program of $\Pi$.

**Example 1 (Continued)** The assumptions for rule $a \times b \leftarrow not \ c$, denoted by $O_1(X_1)$, and the assumptions for rule $b \times c \leftarrow not \ d$, denoted by $O_2(X_2)$ are as follows, where $X_1$ and $X_2$ range over $\{0, 1, 2\}$.

**$O_1(X_1)$:**

$$\begin{align*}
\bot & \leftarrow X_1 = 0, \ body_1 \\
\bot & \leftarrow X_1 > 0, \ not \ body_1 \\
a & \leftarrow body_1, \ X_1 = 1 \\
b & \leftarrow body_1, \ X_1 = 2 \\
\bot & \leftarrow body_1, \ X_1 \neq 1, \ a \\
\bot & \leftarrow body_1, \ X_1 \neq 2, \ not \ a, \ b
\end{align*}$$

**$O_2(X_2)$:**

$$\begin{align*}
\bot & \leftarrow X_2 = 0, \ body_2 \\
\bot & \leftarrow X_2 > 0, \ not \ body_2 \\
b & \leftarrow body_2, \ X_2 = 1 \\
c & \leftarrow body_2, \ X_2 = 2 \\
\bot & \leftarrow body_2, \ X_2 \neq 1, \ b \\
\bot & \leftarrow body_2, \ X_2 \neq 2, \ not \ b, \ c
\end{align*}$$
Π₁ has 9 assumption programs,

\[ O₁(0) \cup O₂(0) \quad O₁(0) \cup O₂(1) \quad O₁(0) \cup O₂(2) \{ c \} \]
\[ O₁(1) \cup O₂(0) \quad O₁(1) \cup O₂(1) \quad O₁(1) \cup O₂(2) \{ a, b \} \]
\[ O₁(2) \cup O₂(0) \quad O₁(2) \cup O₂(1) \quad O₁(2) \cup O₂(2) \{ b \} \]

among which the three assumption programs in the boxes are consistent. Their answer sets are shown together.

An advantage of considering assumption programs over split programs is that the satisfaction degrees—a basis of comparing the candidate answer sets—can be obtained from the assumption degrees with a minor modification (Section 2.3.1). This is in part because each candidate answer set is obtained from only one assumption program whereas the same candidate answer set can be obtained from multiple split programs (e.g., \( \{ b \} \) in Example 1).

### 2.3 Turning LPOD into Standard Answer Set Programs

We define a translation \( \text{lpod2asp}(\Pi) \) that turns an LPOD \( \Pi \) into a standard answer set program.

Let \( \Pi \) be an LPOD of signature \( \sigma \) where \( \Pi_{od} \) contains \( m \) propositional rules with ordered disjunction:

\[
\begin{align*}
1 : & \quad C₁¹ \times \cdots \times Cₙ¹ ← \text{Body}_1 \\
\ldots & \\
2 : & \quad C₁ᵐ \times \cdots \times Cₙᵐ ← \text{Body}_m
\end{align*}
\]

where \( 1, \ldots, m \) are rule indices, and \( n_i ≥ 2 \) for \( 1 ≤ i ≤ m \).

The first-order signature \( \sigma' \) of \( \text{lpod2asp}(\Pi) \) contains \( m \)-ary predicate constant \( a/m \) for each propositional constant \( a \) of \( \sigma \). Besides, \( \sigma' \) contains the following predicate constants not in \( \sigma \):

- \( \text{ap}/m \) (“assumption program”), \( \text{degree}/(m+1) \), \( \text{body}_i/m \) \( i \in \{1, \ldots, m\} \), \( \text{prf}/2 \) (“preferred”), and \( \text{pAS}/m \) (“preferred answer set”). Furthermore, \( \sigma' \) contains the following predicate constants according to each preference criterion:
  - for cardinality-preferred: \( \text{card}/3, \text{equ}/2, \text{degree}/3 \)
  - for inclusion-preferred: \( \text{even}/1, \text{equ}/2, \text{degree}/3 \)
  - for Pareto-preferred: \( \text{equ}/2 \)
  - for penalty-sum-preferred: \( \text{sum}/2 \).

### 2.3.1 Generate Candidate Answer Sets

The first part of the translation \( \text{lpod2asp}(\Pi) \) is to generate all candidate answer sets of \( \Pi \) based on the notion of assumption programs. We use the assumption degree list as a “name space” for each candidate answer set, so that we can compare them in a single answer set program.

1. We use atom \( \text{ap}(x₁, \ldots, xₘ) \) to denote the assumption program whose assumption degree list is \( (x₁, \ldots, xₘ) \). We consider all consistent assumption programs by generating a maximal set of \( \text{ap}(\cdot) \) atoms: \( \text{ap}(x₁, \ldots, xₘ) \) is included in an optimal answer set \(^2\) iff the assumption program

\(^2\) For programs containing weak constraints, an optimal answer set is defined by the penalty that comes from the weak constraints that are violated. (Calimeri et al. 2012)
denoted by \( ap(x_1, \ldots, x_m) \) is consistent.

\[
\{ ap(X_1, \ldots, X_m) : X_1 = 0..n_1, \ldots, X_m = 0..n_m \}.
\]

\( \vdash ap(X_1, \ldots, X_m). \ [−1, X_1, \ldots, X_m] \) \hspace{1cm} (11)

Rule (11) is a weak constraint that maximizes the number of \( ap(\cdot) \) atoms by adding the penalty \(-1\) for each true instance of \( ap(X_1, \ldots, X_m) \). Together with the rules below, these rules ensure that we consider all assumption programs that are consistent and that no candidate answer sets are missed in computing preference relationship in the second part of the translation.

2. We extend each atom to include the assumption degrees \( X_1, \ldots, X_m \), and append atom \( ap(X_1, \ldots, X_m) \) in the bodies of rules.

- For each rule \( Head \leftarrow Body \) in \( \Pi_{reg} \), \( \text{lpod2asp}(\Pi) \) contains

\[
\text{Head}(X_1, \ldots, X_m) \leftarrow ap(X_1, \ldots, X_m), Body(X_1, \ldots, X_m) \tag{12}
\]

where \( \text{Head}(X_1, \ldots, X_m) \) and \( \text{Body}(X_1, \ldots, X_m) \) are obtained from \( \text{Head} \) and \( \text{Body} \) by replacing each atom \( A \) in them with \( A(X_1, \ldots, X_m) \). Each schematic variable \( X_i \) ranges over \( \{0, \ldots, n_i\} \).

- For each rule

\[
C_i^1 \times \cdots \times C_i^{n_i} \leftarrow Body_i
\]

in \( \Pi_{od} \), where \( n \geq 2 \), \( \text{lpod2asp}(\Pi) \) contains

\[
\text{body}_{i\downarrow}(X_1, \ldots, X_m) \leftarrow ap(X_1, \ldots, X_m), Body_{i\downarrow}(X_1, \ldots, X_m) \tag{13}
\]

\[
\downarrow \leftarrow ap(X_1, \ldots, X_m), X_i = 0, \text{body}_{i\downarrow}(X_1, \ldots, X_m) \tag{14}
\]

\[
\downarrow \leftarrow ap(X_1, \ldots, X_m), X_i > 0, \text{not body}_{i\downarrow}(X_1, \ldots, X_m). \tag{15}
\]

And for \( 1 \leq j \leq n_i \), \( \text{lpod2asp}(\Pi) \) contains

\[
C_i^j(X_1, \ldots, X_m) \leftarrow \text{body}_{i\downarrow}(X_1, \ldots, X_m), X_i = j. \tag{16}
\]

\[
\downarrow \leftarrow \text{body}_{i\downarrow}(X_1, \ldots, X_m), X_i \neq j,
\]

\[
\text{not } C_i^j(X_1, \ldots, X_m), \ldots, \text{not } C_i^{j-1}(X_1, \ldots, X_m), C_i^j(X_1, \ldots, X_m). \tag{17}
\]

3. The satisfaction degree list can be obtained from the assumption degree list encoded in \( ap(x_1, \ldots, x_m) \) by changing \( x_i \) to 1 if it was 0. For this, \( \text{lpod2asp}(\Pi) \) contains

\[
1\{\text{degree}(ap(X_1, \ldots, X_m), D_1, \ldots, D_m) : D_1 = 1..n_1, \ldots, D_m = 1..n_m \} \leftarrow ap(X_1, \ldots, X_m). \tag{18}
\]

and for \( 1 \leq i \leq m \), \( \text{lpod2asp}(\Pi) \) contains

\[
\downarrow \leftarrow \text{degree}(ap(X_1, \ldots, X_m), D_1, \ldots, D_m), X_i = 0, D_i \neq 1. \tag{19}
\]

\[
\downarrow \leftarrow \text{degree}(ap(X_1, \ldots, X_m), D_1, \ldots, D_m), X_i > 0, D_i \neq X_i. \tag{20}
\]

Since all answer sets of the same assumption program are associated with the same satisfaction degree list, we say an assumption program satisfies LPD rule \( i \) to degree \( d \) if its answer sets satisfy the rule to degree \( d \). Rule (18) reads “for any assumption program \( ap(x_1, \ldots, x_m) \), it has exactly one assignment of satisfaction degrees \( D_1, \ldots, D_m \)” Rules (19) and (20) say that the
assumption program \( ap(x_1, \ldots, x_m) \) satisfies LPOD rule \( i \) to degree 1 if \( x_i = 0 \) (in which case \( \text{Body}_i \) is false) and to degree \( x_i \) if \( x_i > 0 \) (in which case \( \text{Body}_i \) is true).

Let us denote the set of rules (10)—(20) by \( \text{lpod2asp}(\Pi)_{\text{base}} \). Observe that the atoms \( a(v) \) in the original signature \( \sigma \) are in the form of \( a(v, x_1, \ldots, x_m) \) in the answer sets of \( \text{lpod2asp}(\Pi)_{\text{base}} \).

We define a way to retrieve the candidate answer set of \( \Pi \) by removing \( x_1, \ldots, x_m \) as follows. Let \( S \) be an optimal answer set of \( \text{lpod2asp}(\Pi)_{\text{base}} \), and let
\[
\text{shrink}(S, x_1, \ldots, x_m) = \{ a(v) \mid a(v, x_1, \ldots, x_m) \in S \text{ and } a(v) \in \sigma \}.
\]
If \( S \models ap(x_1, \ldots, x_m) \), we define the set \( \text{shrink}(S, x_1, \ldots, x_m) \) as a candidate answer set on \( \sigma \) of \( \text{lpod2asp}(\Pi)_{\text{base}} \).

The following proposition asserts the soundness of the translation \( \text{lpod2asp}(\Pi)_{\text{base}} \).

**Proposition 2**

The candidate answer sets of an LPOD \( \Pi \) of signature \( \sigma \) are exactly the candidate answer sets on \( \sigma \) of \( \text{lpod2asp}(\Pi)_{\text{base}} \).

**Example 1 Continued:** The following is the encoding of \( \text{lpod2asp}(\Pi_1)_{\text{base}} \) in the input language of CLINGO.

```clingo
% % % % %
{ap(X1,X2): X1=0..2, X2=0..2}. :- ap(X1,X2). [-1, X1, X2]

% % % % % %
% a*b <- not c.
body_1(X1,X2) :- ap(X1,X2), not c(X1,X2).
:- ap(X1,X2), X1=0, body_1(X1,X2).
:- ap(X1,X2), X1>0, not body_1(X1,X2).

a(X1,X2) :- body_1(X1,X2), X1=1.
b(X1,X2) :- body_1(X1,X2), X1=2.

:- body_1(X1,X2), X1!=1, a(X1,X2).
:- body_1(X1,X2), X1!=2, not a(X1,X2), b(X1,X2).

% b*c <- not d.
body_2(X1,X2) :- ap(X1,X2), not d(X1,X2).
:- ap(X1,X2), X2=0, body_2(X1,X2).
:- ap(X1,X2), X2>0, not body_2(X1,X2).

b(X1,X2) :- body_2(X1,X2), X2=1.
c(X1,X2) :- body_2(X1,X2), X2=2.

:- body_2(X1,X2), X2!=1, b(X1,X2).
:- body_2(X1,X2), X2!=2, not b(X1,X2), c(X1,X2).

% % % % % %
1(degree(ap(X1,X2), D1, D2): D1=1..2, D2=1..2)1 :- ap(X1,X2).

:- degree(ap(X1,X2), D1, D2), X1=0, D1!=1.
:- degree(ap(X1,X2), D1, D2), X1>0, D1!=X1.

:- degree(ap(X1,X2), D1, D2), X2=0, D2!=1.
:- degree(ap(X1,X2), D1, D2), X2>0, D2!=X2.
```

3 We also apply this notation to the full translation \( \text{lpod2asp}(\Pi) \) and \( \text{crp2asp}(\Pi) \) below.
The optimal answer set \( S \) of \( \text{lpod2asp}(\Pi_1)_{\text{base}} \) is
\[
\{ ap(1,1), a(1,1), b(1,1), \ldots, ap(2,1), b(2,1), \ldots, ap(0,2), c(0,2), \ldots \}
\]  
\[(21)\]
(bodies and degrees are not listed). Since \( S \) satisfies \( ap(1,1), ap(2,1), \) and \( ap(0,2) \), the candidate answer sets on \( \sigma \) of \( \text{lpod2asp}(\Pi_1)_{\text{base}} \) are
\[
\text{shrink}(S,1,1) = \{ a, b \}, \text{ shrink}(S,2,1) = \{ b \}, \text{ shrink}(S,0,2) = \{ c \}
\]
which are exactly the candidate answer sets of \( \Pi_1 \).

### 2.3.2 Find Preferred Answer Sets

The second part of the translation \( \text{lpod2asp}(\Pi) \) is to compare the candidate answer sets to find the preferred answer sets. For each preference criterion, \( \text{lpod2asp}(\Pi) \) contains the following rules respectively. Below \( \text{maxdegree} \) is \( \max\{ n_i \mid i \in \{ 1, \ldots, m \} \} \).

(a) **Cardinality-Preferred:** For this criterion, \( \text{lpod2asp}(\Pi) \) contains the following rules.
\[
\text{card}(P,X,N) \leftarrow \text{degree}(P,D_1,\ldots,D_m), X = \text{maxdegree},
\]
\[
N = \{ D_1 = X; \ldots; D_m = X \}.
\]  
\[(22)\]
\[
\text{equ2degree}(P_1,P_2,X) \leftarrow \text{card}(P_1,X,N), \text{card}(P_2,X,N), P_1 \neq P_2.
\]  
\[(23)\]
\[
\text{prf2degree}(P_1,P_2,X) \leftarrow \text{card}(P_1, X, N_1), \text{card}(P_2, X, N_2), N_1 > N_2.
\]  
\[(24)\]
\[
\text{prf}(P_1,P_2) \leftarrow X = 0..\text{maxdegree} - 1, \text{prf2degree}(P_1,P_2,X+1),
\]
\[
X\{ \text{equ2degree}(P_1,P_2,Y) : Y = 1..X \}.
\]  
\[(25)\]
\[
\text{pAS}(X_1,\ldots,X_m) \leftarrow \text{ap}(X_1,\ldots,X_m), \{ \text{prf}(P, \text{ap}(X_1,\ldots,X_m)) \} 0.
\]  
\[(26)\]

\( P, P_1, \) and \( P_2 \) denote assumption programs in the form of \( \text{ap}(X_1,\ldots,X_m) \). \( \text{card}(P,X,N) \) is true if \( P \) satisfies \( N \) rules in \( \Pi_{\text{od}} \) to degree \( X \). \( \text{equ2degree}(P_1,P_2,X) \) is true if \( P_1 \) and \( P_2 \) have the same number of rules that are satisfied to degree \( X \). \( \text{prf2degree}(P_1,P_2,X) \) is true if \( P_1 \) satisfies more rules to degree \( X \) than \( P_2 \) does. \( \text{prf}(P_1,P_2) \) is true if \( P_1 \) is cardinality-preferred to \( P_2 \): \( P_1 \) satisfies more rules to degree \( X + 1 \) than \( P_2 \) does whereas they satisfy the same number of rules up to degree \( X \). Rule (26) reads as: given an assumption program represented by \( \text{ap}(X_1,\ldots,X_m) \), if we cannot find an assumption program \( P \) that is more preferable, then the answer sets of \( \text{ap}(X_1,\ldots,X_m) \) are all preferred answer sets of \( \Pi \). Note that \( P \) in rule (26) is a local variable that ranges over all \( \text{ap}(\cdot) \) atoms.

(b) **Inclusion-Preferred:** For this criterion, \( \text{lpod2asp}(\Pi) \) contains the following rules.
\[
\text{even}(0;2).
\]  
\[(27)\]
\[
\text{equ2degree}(P_1,P_2,X) \leftarrow P_1 \neq P_2, X = \text{maxdegree},
\]
\[
\text{degree}(P_1,D_{11},\ldots,D_{1m}), \text{degree}(P_2,D_{21},\ldots,D_{2m}),
\]
\[
C_1 = \{ D_{11} = X; D_{21} = X \}, \ldots, C_m = \{ D_{1m} = X; D_{2m} = X \},
\]
\[
\text{even}(C_1),\ldots,\text{even}(C_m).
\]  
\[(28)\]
\[
\text{prf2degree}(P_1,P_2,X) \leftarrow P_1 \neq P_2, X = \text{maxdegree},
\]
\[
\text{not equ2degree}(P_1,P_2,X),
\]
\[
\text{degree}(P_1,D_{11},\ldots,D_{1m}), \text{degree}(P_2,D_{21},\ldots,D_{2m}),
\]
\[
\{ D_{11} \neq X; D_{21} = X \}, \ldots, \{ D_{1m} \neq X; D_{2m} = X \}.
\]  
\[(29)\]
\[
\text{prf}(P_1,P_2) \leftarrow X = 0..\text{maxdegree} - 1, \text{prf2degree}(P_1,P_2,X+1),
\]
\[
X\{ \text{equ2degree}(P_1,P_2,Y) : Y = 1..X \}.
\]  
\[(30)\]
\[
\text{pAS}(X_1,\ldots,X_m) \leftarrow \text{ap}(X_1,\ldots,X_m), \{ \text{prf}(P, \text{ap}(X_1,\ldots,X_m)) \} 0.
\]  
\[(31)\]
Translating LPOD and CR-Prolog into Standard Answer Set Programs

where \{D_{11} = X; D_{21} = X\} counts the number of true atoms in this set, so it equals to 0 (or 2) when none (or both) of \(D_{11} = X\) and \(D_{21} = X\) are true; \{D_{11} \neq X; D_{21} = X\}\] means that the number of true atoms in this set must be smaller or equal to 1, which means that \(D_{11} \neq X\) and \(D_{21} = X\) cannot be true at the same time – in other words, \(D_{21} = X\) implies \(D_{11} = X\).

(c) **Pareto-Preferred:** For this criterion, \texttt{lpod2asp}(\Pi) contains the following rules.

\[
equ(P_1, P_2) \leftarrow \text{degree}(P_1, D_1, \ldots, D_m), \text{degree}(P_2, D_1, \ldots, D_m).
\]

\[
prf(P_1, P_2) \leftarrow \text{degree}(P_1, D_{11}, \ldots, D_{1m}), \text{degree}(P_2, D_{21}, \ldots, D_{2m}),
\]

\[
\neg \equ(P_1, P_2), D_{11} \leq D_{21}, \ldots, D_{1m} \leq D_{2m}.
\]

\[
pAS(X_1, \ldots, X_m) \leftarrow \text{ap}(X_1, \ldots, X_m), \{\text{prf}(P, \text{ap}(X_1, \ldots, X_m))\}0.
\]

where \equ(P_1, P_2) means that \(P_1\) is equivalent to \(P_2\) at all degrees.

(d) **Penalty-Sum-Preferred:** For this criterion, \texttt{lpod2asp}(\Pi) contains the following rules.

\[
sum(P, N) \leftarrow \text{degree}(P, D_1, \ldots, D_m), N = D_1 + \cdots + D_m.
\]

\[
prf(P_1, P_2) \leftarrow \text{sum}(P_1, N_1), \text{sum}(P_2, N_2), N_1 < N_2.
\]

\[
pAS(X_1, \ldots, X_m) \leftarrow \text{ap}(X_1, \ldots, X_m), \{\text{prf}(P, \text{ap}(X_1, \ldots, X_m))\}0.
\]

where \texttt{sum}(P, N) means that the sum of \(P\)'s satisfaction degrees of all rules is \(N\).

If \(S \models pAS(x_1, \ldots, x_m)\), we define the set \texttt{shrink}(S, x_1, \ldots, x_m) to be a preferred answer set on \(\sigma\) of \texttt{lpod2asp}(\Pi).

The following theorem assert the soundness of the translation \texttt{lpod2asp}(\Pi).

**Theorem 1**

Under any of the four preference criteria, the candidate (preferred, respectively) answer sets of an LPOD \(\Pi\) of signature \(\sigma\) are exactly the candidate (preferred, respectively) answer sets on \(\sigma\) of \texttt{lpod2asp}(\Pi).

**Example 2 Continued:** The first part of \texttt{lpod2asp}(\Pi_2) contains the following rules.

```prolog
%const maxdegree = 4.
%%%% 1 %%%% {ap(X1,X2): X1=0..4, X2=0..3}. :- ap(X1,X2). [-1, X1, X2]
%%%% 2 %%%% l{hotel(H,X1,X2): H=1..3} l :- ap(X1,X2).
:- ap(X1,X2), hotel(1,X1,X2), not close(X1,X2).
:- ap(X1,X2), hotel(1,X1,X2), not star2(X1,X2).
:- ap(X1,X2), hotel(2,X1,X2), not med(X1,X2).
:- ap(X1,X2), hotel(2,X1,X2), not star3(X1,X2).
:- ap(X1,X2), hotel(3,X1,X2), not tooFar(X1,X2).
:- ap(X1,X2), hotel(3,X1,X2), not star4(X1,X2).

% close * med * far * tooFar.

body_1(X1,X2) :- ap(X1,X2).
```
:- ap(X1, X2), X1 = 0, body_1(X1, X2).
:- ap(X1, X2), X1 > 0, not body_1(X1, X2).

close(X1, X2) :- body_1(X1, X2), X1 = 1.
med(X1, X2) :- body_1(X1, X2), X1 = 2.
far(X1, X2) :- body_1(X1, X2), X1 = 3.
tooFar(X1, X2) :- body_1(X1, X2), X1 = 4.

:- body_1(X1, X2), X1 != 1, close(X1, X2).
:- body_1(X1, X2), X1 != 2, not close(X1, X2), med(X1, X2).
:- body_1(X1, X2), X1 != 3, not close(X1, X2), not med(X1, X2), far(X1, X2).
:- body_1(X1, X2), X1 != 4, not close(X1, X2), not med(X1, X2), not far(X1, X2),
tooFar(X1, X2).

% star4 * star3 * star2.

body_2(X1, X2) :- ap(X1, X2).

:- ap(X1, X2), X2 = 0, body_2(X1, X2).
:- ap(X1, X2), X2 > 0, not body_2(X1, X2).

star4(X1, X2) :- body_2(X1, X2), X2 = 1.
star3(X1, X2) :- body_2(X1, X2), X2 = 2.
star2(X1, X2) :- body_2(X1, X2), X2 = 3.

:- body_2(X1, X2), X2 != 1, star4(X1, X2).
:- body_2(X1, X2), X2 != 2, not star4(X1, X2), star3(X1, X2).
:- body_2(X1, X2), X2 != 3, not star4(X1, X2), not star3(X1, X2), star2(X1, X2).

%%%% 3 %%%% 1{ degree(ap(X1, X2), D1, D2) : D1=1..4, D2=1..3} % ap(X1, X2).

:- degree(ap(X1, X2), D1, D2), X1 = 0, D1 != 1.
:- degree(ap(X1, X2), D1, D2), X1 > 0, D1 = 1.

:- degree(ap(X1, X2), D1, D2), X2 = 0, D2 = 1.
:- degree(ap(X1, X2), D1, D2), X2 > 0, D2 = 2.

For the second part of the translation, lpod2asp(Π2) contains one of the following sets of rules.

%%%% a. Cardinality %%%%
card(P, X, N) :- degree(P, D1, D2), X = 1..maxdegree, N = {D1=X; D2=X}.
equ2degree(P1, P2, X) :- card(P1, X, N1), card(P2, X, N2), P1 != P2.
prf2degree(P1, P2, X) :- card(P1, X, N1), card(P2, X, N2), N1 > N2.
prf(P1, P2) :- X = 0..maxdegree-1, prf2degree(P1, P2, X+1), X {equ2degree(P1, P2, Y) : Y = 1..X}.
pAS(X1, X2) :- ap(X1, X2), {prf(P, ap(X1, X2))}.

%%%% b. Inclusion %%%%
even(0; 2).
equ2degree(P1, P2, X) :- P1 = P2, X = 1..maxdegree, degree(P1, D11, D12), degree(P2, D21, D22),
C1 = (D11 = X; D21 = X), C2 = (D12 = X; D22 = X), even(C1), even(C2).
prf2degree(P1, P2, X) :- P1 = P2, X = 1..maxdegree, not equ2degree(P1, P2, X),
degree(P1, D11, D12), degree(P2, D21, D22),
(D11 = X; D21 = X), (D12 = X; D22 = X).
prf(P1, P2) :- X = 0..maxdegree-1, prf2degree(P1, P2, X+1), X {equ2degree(P1, P2, Y) : Y = 1..X}.
pAS(X1, X2) :- ap(X1, X2), {prf(P, ap(X1, X2))}.
Translating LPOD and CR-Prolog into Standard Answer Set Programs

%%% c. Pareto %%%

equ(P1, P2) :- degree(P1, D11, D12), degree(P2, D11, D12).

prf(P1, P2) :- degree(P1, D11, D12), degree(P2, D21, D22), not equ(P1, P2),

    D11 <= D21, D12 <= D22.

pAS(X1, X2) :- ap(X1, X2), {prf(P, ap(X1, X2))}0.

%%% d. Penalty-Sum %%%

sum(P, N) :- degree(P, D1, D2), N = D1 + D2.

prf(P1, P2) :- sum(P1, N1), sum(P2, N2), N1 < N2.

pAS(X1, X2) :- ap(X1, X2), {prf(P, ap(X1, X2))}0.

Note that each set of rules in the second part conservatively extends the answer set of the base program. For example, the optimal answer set of \( \text{lpod2asp}(\Pi_1) \) under Penalty-Sum preference is the union of (21) and \( \{\text{sum}(\text{ap}(0, 2), 3), \text{sum}(\text{ap}(1, 1), 2), \text{sum}(\text{ap}(2, 1), 3), \text{prf}(\text{ap}(1, 1), \text{ap}(0, 2)), \text{prf}(\text{ap}(1, 1), \text{ap}(2, 1)), \text{pAS}(1, 1)\} \), which indicates that \( \{a, b\} \) is the preferred answer set.

The optimal answer set \( S \) of \( \text{lpod2asp}(\Pi_2) \) under the cardinality preference is

\[
\{ \text{pAS}(1, 3), \text{ap}(1, 3), \text{hotel}(1, 1, 3), \text{close}(1, 3), \text{star}(2, 1, 3), \text{ap}(2, 2), \text{hotel}(2, 2, 2), \text{med}(2, 2), \text{star}(3, 2, 2), \text{ap}(4, 1), \text{hotel}(3, 4, 1), \text{tooFar}(4, 1), \text{star}(4, 1) \ldots \}
\]

Since \( S \) satisfies \( \text{ap}(1, 3), \text{ap}(2, 2), \text{and} \text{ap}(4, 1) \), the candidate answer sets on \( \sigma \) of \( \text{lpod2asp}(\Pi_2) \) are

\[
\begin{align*}
\text{shrink}(S, 1, 3) &= \{\text{hotel}(1), \text{close}, \text{star}(2)\}, \\
\text{shrink}(S, 2, 2) &= \{\text{hotel}(2), \text{med}, \text{star}(3)\}, \\
\text{shrink}(S, 4, 1) &= \{\text{hotel}(3), \text{tooFar}, \text{star}(4)\},
\end{align*}
\]

which are exactly the candidate answer sets of \( \Pi_2 \). Since \( S \) satisfies \( \text{pAS}(1, 3) \), the preferred answer sets on \( \sigma \) of \( \text{lpod2asp}(\Pi_2) \) is \( \text{shrink}(S, 1, 3) = \{\text{hotel}(1), \text{close}, \text{star}(2)\} \) which is exactly the cardinality-preferred answer set of \( \Pi_2 \). Let

\[
\begin{align*}
\text{pAS}_1 &= \{\text{pAS}(1, 3), \text{hotel}(1, 1, 3), \text{close}(1, 3), \text{star}(2, 1, 3)\}, \\
\text{pAS}_2 &= \{\text{pAS}(2, 2), \text{hotel}(2, 2, 2), \text{med}(2, 2), \text{star}(3, 2, 2)\}, \\
\text{pAS}_3 &= \{\text{pAS}(4, 1), \text{hotel}(3, 4, 1), \text{tooFar}(4, 1), \text{star}(4, 1)\}.
\end{align*}
\]

The optimal answer sets of \( \text{lpod2asp}(\Pi_2) \) under 4 criteria contain

\[
\text{cardinality-preferred: } \text{pAS}_1 \quad \text{inclusion-preferred: } \text{pAS}_1 \cup \text{pAS}_3 \\
\text{Pareto-preferred: } \text{pAS}_1 \cup \text{pAS}_2 \cup \text{pAS}_3 \quad \text{penalty-sum-preferred: } \text{pAS}_1 \cup \text{pAS}_2
\]

which are in a 1-1 correspondence with the preferred answer sets of \( \Pi_2 \) under each of the four criteria respectively.

3 CR-Prolog to ASP with Weak Constraints

3.1 Review: CR-Prolog

We review the definition of CR-Prolog from (Balduccini et al. 2003).
Syntax: A (propositional) CR-Prolog$_2$ program $Π$ consists of four kinds of rules:

<table>
<thead>
<tr>
<th>Rule Type</th>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>regular rule</td>
<td>$Head ← Body$</td>
</tr>
<tr>
<td>ordered rule</td>
<td>$i : C^i_1 × ⋯ × C^i_{n_i} ← Body$</td>
</tr>
<tr>
<td>cr-rule</td>
<td>$i : Head ⇝ Body$</td>
</tr>
<tr>
<td>ordered cr-rule</td>
<td>$i : C^i_1 × ⋯ × C^i_{n_i} ⇝ Body$</td>
</tr>
</tbody>
</table>

where $Head ← Body$ is a standard ASP rule, $i$ is the index of the rule, $C^i_j$ are atoms, and $n_i ≥ 2$. The intuitive meaning of an ordered disjunction $C^i_1 × ⋯ × C^i_{n_i}$ is similar to the one for LPOD. A cr-rule (40) or an ordered cr-rule (41) is applied in $Π$ if it is treated as a usual ASP rule in $Π$ (by replacing $⇝$ with $←$); it is not applied if it is omitted in $Π$. A cr-rule (40) or an ordered cr-rule (41) is applied only if the agent has no way to obtain a consistent set of beliefs using regular rules or ordered rules only. By $Head(i)$ and $Body(i)$, we denote the head and the body of rule $i$.

Semantics: The semantics of CR-Prolog$_2$ is based on the transformation from a CR-Prolog$_2$ program $Π$ of signature $σ$ into an answer set program $H_Π$, which is constructed as follows. The first-order signature of $H_Π$ is $σ ∪ \{choice/2, appl/1, fired/1, isPreferred/2\}$, where $choice$ is a function constant, $appl, fired, isPreferred$ are predicate constants not in $σ$.

1. Let $R_Π$ be the set of rules obtained from $Π$ by replacing every cr-rule and ordered cr-rule of index $i$ with a rule:

$$i : Head(i) ← Body(i), appl(i)$$

where $appl(i)$ means rule $i$ is applied. Notice that $R_Π$ contains only regular rules and ordered rules.

$H_Π$ is then obtained from $R_Π$ by replacing every ordered rule of index $r$, where $Head(r) = C^r_1 × ⋯ × C^r_{n_r}$, with the following rules (for $1 ≤ j ≤ n_i$):

$$C^r_j ← Body(r), appl(choice(r, j))$$
$$fired(r) ← appl(choice(r, j))$$
$$prefer(choice(r, j), choice(r, j + 1)) (j < n_i)$$
$$⊥ ← Body(r), not fired(r)$$

where $appl(choice(r, j))$ means that the $j$-th atom in the ordered disjunction $Head(r)$ is chosen, i.e., $C^r_j$ is true if $Head(r)$ is true.

2. $H_Π$ also contains the following set of rules:

$$isPreferred(R_1, R_2) ← prefer(R_1, R_2).$$
$$isPreferred(R_1, R_3) ← prefer(R_1, R_2), isPreferred(R_2, R_3).$$
$$⊥ ← isPreferred(R, R).$$
$$⊥ ← appl(R_1), appl(R_2), isPreferred(R_1, R_2).$$

where $R_1, R_2, R_3$ are schematic variables ranging over indices of cr-rules and ordered cr-rules in $Π$ as well as terms of the form $choice(\cdot)$.

By $atoms(H_Π, \{appl\})$, we denote the set of atoms in $H_Π$ in the form of $appl(\cdot)$. A generalized answer set of $Π$ is an answer set of $H_Π ⊔ A$ where $A ⊆ atoms(H_Π, \{appl\})$.

Let $S_1, S_2$ be generalized answer sets of $Π$. $S_1$ dominates $S_2$ if there exist $r_1$ and $r_2$ such that $appl(r_1) ∈ S_1$, $appl(r_2) ∈ S_2$, and $isPreferred(r_1, r_2) ∈ S_1 ∩ S_2$. Further, we say this domination is rule-wise if $r_1$ and $r_2$ are indices of two cr-rules; atom-wise if $r_1$ and $r_2$ are two
terms of the form $\text{choice}()$. $S_1$ is a candidate answer set of $\Pi$ if there is no other generalized answer set that dominates $S_1$.

The projection of $S_1$ onto $\sigma$ is a preferred answer set of $\Pi$ if $S_1$ is a candidate answer set of $\Pi$ and there is no other candidate answer set $S_2$ such that $S_2 \cap \text{atoms}(H_{\Pi_1}, \{\text{appl}\}) \subset S_1$.

Example 3
(From Balduccini et al. 2003) Consider the following CR-Prolog program $\Pi_3$:

$$
\begin{align*}
q & \leftarrow t. \\
\text{isPreferred}(1) & \leftarrow t \leftarrow. \\
p & \leftarrow \text{not } q. \\
r & \leftarrow \text{not } s. \\
\text{Body} & \leftarrow p, r.
\end{align*}
$$

which has 5 generalized answer sets (the atoms formed by isPreferred or fired are omitted)

$$
S_1 = \{q, s, t, \text{appl}(1), \text{prefer}(\text{choice}(2, 1), \text{choice}(2, 2))\}
$$

$$
S_2 = \{q, r, \text{appl}(2), \text{appl}(\text{choice}(2, 1), \text{prefer}(\text{choice}(2, 1), \text{choice}(2, 2)))\}
$$

$$
S_3 = \{p, s, \text{appl}(2), \text{appl}(\text{choice}(2, 2), \text{prefer}(\text{choice}(2, 1), \text{choice}(2, 2)))\}
$$

$$
S_4 = \{q, s, t, \text{appl}(1), \text{appl}(2), \text{appl}(\text{choice}(2, 1), \text{prefer}(\text{choice}(2, 1), \text{choice}(2, 2)))\}
$$

$$
S_5 = \{q, s, t, \text{appl}(1), \text{appl}(2), \text{appl}(\text{choice}(2, 1), \text{prefer}(\text{choice}(2, 1), \text{choice}(2, 2)))\}
$$

Since $S_2$ (atom-wise) dominates $S_3$ and $S_5$, the candidate answer sets are $S_1$, $S_2$, and $S_4$. Since $S_1 \cap \text{atoms}(H_{\Pi_1}, \{\text{appl}\}) \subset S_4$, the preferred answer sets of $\Pi_3$ are the projections from $S_1$ or $S_2$ onto $\sigma$.

### 3.2 Turning CR-Prolog into ASP with Weak Constraints

We define a translation crp2asp($\Pi$) that turns a CR-Prolog program $\Pi$ into an answer set program with weak constraints.

Let $\Pi$ be a CR-Prolog program of signature $\sigma$, where its rules are rearranged such that the cr-rules are of indices $1, \ldots, k$, the ordered cr-rules are of indices $k + 1, \ldots, l$, and the ordered rules are of indices $l + 1, \ldots, m$.

For an ordered rule (39) or an ordered cr-rule (41), its $i$-th assumption, where $i \in \{1, \ldots, n_i\}$, is defined as $C^i \leftarrow \text{Body}$. An assumption program $AP(x_1, \ldots, x_m)$ of $\Pi$ whose assumption degree list is $(x_1, \ldots, x_m)$ is obtained from $\Pi$ as follows ($x_i \in \{0, 1\}$ if $i = 1, \ldots, k$; $x_i \in \{0, \ldots, n_i\}$ if $i = k + 1, \ldots, l$; $x_i \in \{1, \ldots, n_i\}$ if $i = l + 1, \ldots, m$, where $n_i$ is the number of atoms in the head of rule $i$).

- every regular rule (38) is in $AP(x_1, \ldots, x_m)$;
- a cr-rule (40) is omitted if $x_i = 0$, and is replaced by $\text{Head} \leftarrow \text{Body}$ if $x_i = 1$;
- an ordered cr-rule (41) is omitted if $x_i = 0$, and is replaced by its $x_i$-th assumption if $x_i > 0$;
- an ordered rule (39) is replaced by its $x_i$-th assumption.

Besides, each assumption program $AP(x_1, \ldots, x_m)$ contains

$$
\begin{align*}
isPreferred(R1, R2) & \leftarrow \text{prefer}(R1, R2). \\
isPreferred(R1, R3) & \leftarrow \text{prefer}(R1, R2), \text{isPreferred}(R2, R3). \\
isPreferred(R, R) & \leftarrow \text{isPreferred}(R, R). \\
\text{Body} & \leftarrow x_{r_1} > 0, x_{r_2} > 0, \text{isPreferred}(r_1, r_2). \quad (1 \leq r_1, r_2 \leq l)
\end{align*}
$$

The generalized answer sets of $\Pi$ can be obtained from the answer sets of all the assumption programs of $\Pi$. 
Proposition 3
For any CR-Prolog₂ program \( \Pi \) of signature \( \sigma \), a set \( X \) of atoms is the projection of a generalized answer set of \( \Pi \) onto \( \sigma \) iff \( X \) is the projection of an answer set of an assumption program of \( \Pi \) onto \( \sigma \).

Let \( \Pi_1 \) and \( \Pi_2 \) be two assumption programs of \( \Pi \). We say an answer set \( S_1 \) of \( \Pi_1 \) dominates an answer set \( S_2 \) of \( \Pi_2 \) if (i) there exists a rule \( i \) in \( \Pi_1 \) that is replaced by its \( j_1 \)-th assumption in \( \Pi_1 \), is replaced by its \( j_2 \)-th assumption in \( \Pi_2 \), and \( j_1 < j_2 \); or (ii) there exist 2 rules \( r_1, r_2 \) in \( \Pi \) such that \( r_1 \) is applied in \( \Pi_1 \), \( r_2 \) is applied in \( \Pi_2 \), and \( \text{prefer}(r_1, r_2) \in S_1 \cap S_2 \). Indeed, by Proposition 3, \( S_1 \) dominates \( S_2 \) iff the corresponding generalized answer set of the former dominates that of the latter.

An answer set program with weak constraints \( \text{crp2asp}(\Pi) \) is obtained from \( \Pi \) based on the notion of assumption programs as follows. The first-order signature \( \sigma' \) of \( \text{crp2asp}(\Pi) \) contains \( m \)-ary predicate constant \( a/m \) for each propositional constant \( a \) of \( \sigma \). Besides, \( \sigma' \) contains the following predicate constants not in \( \sigma \): \( \text{ap}/m \), \( \text{dominate}/2 \), \( \text{isPreferred}/(m+2) \), \( \text{candidate}/m \), \( \text{lessCrRulesApplied}/2 \), and \( \text{pAS}/m \).

1. To consider a maximal set of consistent assumption programs, \( \text{crp2asp}(\Pi) \) contains

\[
\{ \text{ap}(X_1, \ldots, X_m) : X_1 = 0..1, \ldots, X_k = 0..1, X_{k+1} = 0..n_{k+1}, \ldots, X_l = 0..n_l, X_{l+1} = 1..n_{l+1}, \ldots, X_m = 1..n_m \}.
\]

\[
: \sim \text{ap}(X_1, \ldots, X_m). [-1, X_1, \ldots, X_m]
\]

where \( n_i \) is the number of atoms in \( \text{Head}(i) \), \( \text{ap}(X_1, \ldots, X_m) \) denotes an assumption program obtained from \( \Pi \).

2. \( \text{crp2asp}(\Pi) \) contains the following rules to construct all assumption programs \( AP(x_1, \ldots, x_m) \):

- for each regular rule \( \text{Head} \leftarrow \text{Body} \) in \( \Pi \), \( \text{crp2asp}(\Pi) \) contains

\[
\text{Head}(X_1, \ldots, X_m) \leftarrow \text{ap}(X_1, \ldots, X_m), \text{Body}(X_1, \ldots, X_m)
\]

(45)

- for each cr-rule \( i : \text{Head}_i \leftarrow \text{Body}_i \) in \( \Pi \), \( \text{crp2asp}(\Pi) \) contains

\[
\text{Head}_i(X_1, \ldots, X_m) \leftarrow \text{ap}(X_1, \ldots, X_m), \text{Body}_i(X_1, \ldots, X_m), X_i = 1
\]

(46)

- for each ordered rule or ordered cr-rule \( i : C^1_i \times \cdots \times C^n_i \leftarrow \text{Body}_i \) in \( \Pi \), for \( 1 \leq j \leq n_i \), \( \text{crp2asp}(\Pi) \) contains

\[
C^j_i(X_1, \ldots, X_m) \leftarrow \text{ap}(X_1, \ldots, X_m), \text{Body}_i(X_1, \ldots, X_m), X_i = j
\]

(47)

3. To define \( \text{dominate} \) in the semantics of CR-Prolog₂, \( \text{crp2asp}(\Pi) \) contains the following rules.

**Atom-wise dominance:** Instead of using choice(\( \cdot \)) terms and \( \text{appl}(\text{choice}(\cdot)) \) atoms in (42), we represent the atom wise dominance by comparing the assumption degrees. For ordered cr-rules and ordered rules \( i \in \{ k+1, \ldots, m \} \), we include

\[
\text{dominate}(\text{ap}(X_1, \ldots, X_m), \text{ap}(Y_1, \ldots, Y_m)) \leftarrow \text{ap}(X_1, \ldots, X_m), \text{ap}(Y_1, \ldots, Y_m), 0 < X_i, X_i < Y_i
\]

(48)

**Rule-wise dominance:** The following rules are included only when \( \Pi \) contains an atom \( \text{prefer}(\cdot) \).
To define candidate answer sets in the semantics of CR-Prolog

We say an assumption program \( \Pi_1 \) dominates an assumption program \( \Pi_2 \) if an answer set of \( \Pi_1 \) dominates an answer set of \( \Pi_2 \). Indeed, our translation guarantees that if \( \Pi_1 \) dominates \( \Pi_2 \), all answer sets of \( \Pi_1 \) dominates any answer sets of \( \Pi_2 \). Rule (48) says that the assumption program \( AP(x_1, \ldots, x_m) \) dominates the assumption program \( AP(y_1, \ldots, y_m) \) if there exists a rule \( i \) in \( \Pi \) that is replaced by its \( x_i \)-th assumption in \( AP(x_1, \ldots, x_m) \), by its \( y_i \)-th assumption in \( AP(y_1, \ldots, y_m) \), and \( x_i < y_i \). Rules (49), (50), (51), (52) are the set of rules in the semantics of CR-Prolog with the extended signature \( \sigma' \). Rule (53) says that \( AP(x_1, \ldots, x_m) \) dominates \( AP(y_1, \ldots, y_m) \) if \( isPreferred(r_1, r_2) \) is true in both assumption programs while \( r_1 \) is applied in \( AP(x_1, \ldots, x_m) \) and \( r_2 \) is applied in \( AP(y_1, \ldots, y_m) \).

4. To define candidate answer sets in the semantics of CR-Prolog, \( crp2asp(\Pi) \) contains

\[
\text{isPreferred}(R_1, R_2, X_1, \ldots, X_m) \leftarrow \text{prefer}(R_1, R_2, X_1, \ldots, X_m)
\]
\[
\text{isPreferred}(R_1, R_3, X_1, \ldots, X_m) \leftarrow \text{prefer}(R_1, R_2, X_1, \ldots, X_m),
\]
\[
\text{isPreferred}(R_2, R_3, X_1, \ldots, X_m)
\]
\[
\leftarrow \text{isPreferred}(R, R, X_1, \ldots, X_m)
\]
\[
\leftarrow \text{isPreferred}(r_1, r_2, X_1, \ldots, X_m), X_{r_1} > 0, X_{r_2} > 0
\]
\[
\text{dominate}(ap(X_1, \ldots, X_m), ap(Y_1, \ldots, Y_m)) \leftarrow ap(X_1, \ldots, X_m), ap(Y_1, \ldots, Y_m),
\]
\[
\text{isPreferred}(r_1, r_2, X_1, \ldots, X_m), \text{isPreferred}(r_1, r_2, Y_1, \ldots, Y_m), X_{r_1} > 0, Y_{r_2} > 0
\]

5. To define the preference between two candidate answer sets and find preferred answer sets, \( crp2asp(\Pi) \) contains

\[
\text{lessCrRulesApplied}(ap(X_1, \ldots, X_m), ap(Y_1, \ldots, Y_m)) \leftarrow
\]
\[
\text{candidate}(X_1, \ldots, X_m), \text{candidate}(Y_1, \ldots, Y_m),
\]
\[
1\{X_1 \neq Y_1; \ldots; X_m \neq Y_m\}, X_1 \leq Y_1, \ldots, X_m \leq Y_m
\]
\[
pAS(X_1, \ldots, X_m) \leftarrow \text{candidate}(X_1, \ldots, X_m), (\text{lessCrRulesApplied}(P, ap(X_1, \ldots, X_m)))
\]

Rule (55) says that for any different assumption programs \( AP(x_1, \ldots, x_m) \) and \( AP(y_1, \ldots, y_m) \) whose answer sets are candidate answer sets, if all the choices in \( AP(x_1, \ldots, x_m) \) is not worse than \(^4\) those in \( AP(y_1, \ldots, y_m) \), then the former must apply less cr-rules or ordered cr-rules than the latter. Rule (56) says that the answer sets of \( AP(x_1, \ldots, x_m) \) are preferred answer sets if these answer sets are candidate answer sets and there does not exist an assumption program \( P \) that applies less cr-rules than \( AP(x_1, \ldots, x_m) \).

Let \( S \) be an optimal answer set of \( crp2asp(\Pi) \); \( x_1, \ldots, x_m \) be a list of integers. If \( S \models ap(x_1, \ldots, x_m) \), we define the set \( shrink(S, x_1, \ldots, x_m) \) as a generalized answer set on \( \sigma \) of \( crp2asp(\Pi) \); if \( S \models \text{candidate}(x_1, \ldots, x_m) \), we define the set \( shrink(S, x_1, \ldots, x_m) \) as a candidate answer set on \( \sigma \) of \( crp2asp(\Pi) \); if \( S \models pAS(x_1, \ldots, x_p) \), we define the set \( shrink(S, x_1, \ldots, x_p) \) as a preferred answer set on \( \sigma \) of \( crp2asp(\Pi) \).

\(^4\) i.e., for any rule \( i \) in \( \Pi \), if it is applied in \( AP(x_1, \ldots, x_m) \), it must be applied in \( AP(y_1, \ldots, y_m) \); if it is replaced by its \( x_i \)-th assumption in \( AP(x_1, \ldots, x_m) \), it must be replaced by its \( y_i \)-th assumption in \( AP(y_1, \ldots, y_m) \) and \( x_i \leq y_i \).
**Theorem 2**

For any CR-Prolog program \( \Pi \) of signature \( \sigma \), (a) the projections of the generalized answer sets of \( \Pi \) onto \( \sigma \) are exactly the generalized answer sets on \( \sigma \) of \( \text{crp2asp}(\Pi) \). (b) the projections of the candidate answer sets of \( \Pi \) onto \( \sigma \) are exactly the candidate answer sets on \( \sigma \) of \( \text{crp2asp}(\Pi) \). (c) the preferred answer sets of \( \Pi \) are exactly the preferred answer sets on \( \sigma \) of \( \text{crp2asp}(\Pi) \).

**Example 3 Continued:** The translated ASP program \( \text{crp2asp}(\Pi_3) \) is

\[
\begin{align*}
% 1 & \% \% \%
& (\text{ap}(X_1,X_2) : X_1=0..1, X_2=0..2). \\
& \sim \text{ap}(X_1,X_2). [-1,X_1,X_2] \\
% 2 & \% \% \%
& \text{q}(X_1,X_2) :- \text{ap}(X_1,X_2), \text{t}(X_1,X_2). \\
& \text{s}(X_1,X_2) :- \text{ap}(X_1,X_2), \text{t}(X_1,X_2). \\
& \text{p}(X_1,X_2) :- \text{ap}(X_1,X_2), \text{not} \ \text{q}(X_1,X_2). \\
& \text{r}(X_1,X_2) :- \text{ap}(X_1,X_2), \text{not} \ \text{s}(X_1,X_2). \\
& % 1: \text{t} <-. \\
& \text{t}(X_1,X_2) :- \text{ap}(X_1,X_2), X_1=1. \\
& % 2: \text{q}s <-. \\
& \text{q}(X_1,X_2) :- \text{ap}(X_1,X_2), X_2=1. \\
& \text{s}(X_1,X_2) :- \text{ap}(X_1,X_2), X_2=2. \\
% 3 & \% \% \%
& \text{dominate} (\text{ap}(X_1,X_2), \text{ap}(Y_1,Y_2)) :- \text{ap}(X_1,X_2), \text{ap}(Y_1,Y_2), 0<X_1, X_1 <Y_1. \\
& \text{dominate} (\text{ap}(X_1,X_2), \text{ap}(Y_1,Y_2)) :- \text{ap}(X_1,X_2), \text{ap}(Y_1,Y_2), 0<X_2, X_2 <Y_2. \\
% 4 & \% \% \%
& \text{candidate}(X_1,X_2) :- \text{ap}(X_1,X_2), \{\text{dominate}(P,\text{ap}(X_1,X_2))\}0. \\
% 5 & \% \% \%
& \text{lessCrRulesApplied}(\text{ap}(X_1,X_2), \text{ap}(Y_1,Y_2)) :- \text{candidate}(X_1,X_2), \text{candidate}(Y_1,Y_2), \\
& \quad 1\{X_1=Y_1;X_2=Y_2\}, X_1<=Y_1, X_2<=Y_2. \\
& \text{pAS}(X_1,X_2) :- \text{candidate}(X_1,X_2), \{\text{lessCrRulesApplied}(P,\text{ap}(X_1,X_2))\}0.
\end{align*}
\]

The optimal answer set \( S \) of \( \text{crp2asp}(\Pi_3) \) is

\[
\{\text{pAS}(1,0), \text{candidate}(1,0), \text{ap}(1,0), \text{t}(1,0), \text{q}(1,0), \text{s}(1,0), \text{pAS}(0,1), \text{candidate}(0,1), \text{ap}(0,1), \text{q}(0,1), \text{r}(0,1), \text{ap}(0,2), \text{p}(0,2), \text{s}(0,2), \text{candidate}(1,1), \text{ap}(1,1), \text{t}(1,1), \text{q}(1,1), \text{s}(1,1), \text{ap}(1,2), \text{t}(1,2), \text{q}(1,2), \text{s}(1,2)\ldots\}.
\]

Since \( S \) satisfies \( \text{ap}(1,0), \text{ap}(0,1), \text{ap}(0,2), \text{ap}(1,1), \text{ap}(1,2) \), the generalized answer sets on \( \sigma \) of \( \text{crp2asp}(\Pi_3) \) are

\[
\begin{align*}
\text{shrink}(S,1,0) &= \{t,q,s\} & \text{shrink}(S,1,1) &= \{t,q,s\} \\
\text{shrink}(S,0,1) &= \{q,r\} & \text{shrink}(S,1,2) &= \{t,q,s\} \\
\text{shrink}(S,0,2) &= \{p,s\}
\end{align*}
\]

which are exactly the projections of the generalized answer sets of \( \Pi_3 \) onto \( \sigma \). Similarly, we observe that the candidate (preferred, respectively) answer sets on \( \sigma \) of \( \text{crp2asp}(\Pi_3) \) are exactly the projections of the candidate (preferred, respectively) answer sets of \( \Pi_3 \) onto \( \sigma \).

Furthermore, let \( \Pi'_3 = \Pi_3 \cup \{\text{prefer}(2,1)\} \). The translation \( \text{crp2asp}(\Pi'_3) \) is \( \text{crp2asp}(\Pi_3) \cup R \), where \( R \) is the set of the following rules:
Translating LPOD and CR-Prolog\textsubscript{2} into Standard Answer Set Programs

```prolog
%%% 2 %%% prefer(2,1,X1,X2) :- ap(X1,X2).

%%% 3 %%% isPreferred(R1,R2,X1,X2) :- prefer(R1,R2,X1,X2).
isPreferred(R1,R3,X1,X2) :- prefer(R1,R2,X1,X2), isPreferred(R2,R3,X1,X2).
:- isPreferred(R,R,X1,X2).
:- isPreferred(2,1,X1,X2), X2>0, X1>0.
dominate(ap(X1,X2), ap(Y1,Y2)) :- ap(X1,X2), ap(Y1,Y2),
                           isPreferred(2,1,X1,X2), isPreferred(2,1,Y1,Y2), X2>0, Y1>0.
```

The optimal answer set $S$ of crp2asp($\Pi'$\textsubscript{3}) is

$$\{ \text{ap}(1,0), \text{t}(1,0), \text{q}(1,0), \text{s}(1,0), \text{pAS}(0,1), \text{candidate}(0,1), \text{ap}(0,1), \text{q}(0,1), \text{r}(0,1), \text{ap}(0,2), \text{p}(0,2), \text{s}(0,2), ... \}$$

and it is easy to check that the generalized (/candidate/preferred) answer sets on $\sigma$ of crp2asp($\Pi'$\textsubscript{3}) are exactly the projections of the generalized (/candidate/preferred) answer sets of $\Pi'$\textsubscript{3} onto $\sigma$.

### 4 Related Work and Conclusion

We presented reductions of LPOD and CR-Prolog\textsubscript{2} into the standard ASP language, which explains the new constructs for preference handling in terms of the standard ASP language. The one-pass translations are theoretically interesting. They may be a useful tool for studying the mathematical properties of LPOD and CR-Prolog\textsubscript{2} programs by reducing them to more well-known properties of standard answer set programs. Both translations are “almost” modular in the sense that the translations are rule-by-rule but the argument of each atom representing the assumption degrees may need to be expanded when new rules are added.

However, the direct implementations may not lead to effective implementations. The size of lpod2asp($\Pi$) and crp2asp($\Pi$) after grounding could be exponential to the size of the non-regular rules in $\Pi$. This is because these translations compare all possible assumption programs whose number is exponential to the size of non-regular rules. One may consider parallelizing the computation of assumption programs since they are disjoint from each other according to the translations.

In a sense, our translations are similar to the meta-programming approach to handle preference in ASP (e.g., (Delgrande et al. 2003)) in that we turn LPOD and CR-Prolog\textsubscript{2} into answer set programs that do not have the built-in notion of preference.

In (Brewka et al. 2002), LPOD is implemented using SMODELS. The implementation interleaves the execution of two programs—a generator which produces candidate answer sets and a tester which checks whether a given candidate answer set is maximally preferred or produces a more preferred candidate if it is not. An implementation of CR-Prolog reported in (Balduccini 2007) uses a similar algorithm. In contrast, the reductions shown in this paper can be computed by calling an answer set solver one time without the need for iterating the generator and the tester. This feature may be useful for debugging LPOD and CR-Prolog\textsubscript{2} programs because it allows us to compare all candidate and preferred answer sets globally.

Asprin (Brewka et al. 2015) provides a flexible way to express various preference relations.
over answer sets and is implemented in CLINGO. Similar to the existing LPOD solvers, CLINGO makes iterative calls to find preferred answer sets, unlike the one-shot execution as we do.

Asuncion et al. (2014) presents a first-order semantics of logic programs with ordered disjunction by translation into second-order logic whereas our translation is into the standard answer set programs.
